COMMISSIONER

The Commonwealth of Massachusetts

Department of Public Health

600 Washington Street

Boston 02111

The 1985 and 1990 Population Projections by Sex and Age for Massachusetts Cities and Towns within Health Service Areas have been developed by the Division of Health Statistics and Research. They were formally adopted by the Public Health Council on January 25, 1983, for official use by the Massachusetts Department of Public Health.

Any questions regarding the preparation or use of these projections should be directed to Robert A. Danley, Ph.D., who was responsible for their development, at 80 Boylston Street, Room 335, Boston, Massachusetts 02116, (617) 727-2977.

1985 and 1990 POPULATION PROJECTIONS BY SEX AND AGE

FOR MASSACHUSETTS CITIES and TOWNS WITHIN HEALTH SERVICE AREAS

The Massachusetts Department of Public Health requires population projections by sex and age for the Commonwealth's 351 municipalities for multiple purposes, including health status assessment, program planning, and the implementation of the Determination of Need Program. No federal agency currently provides a standard methodology for projecting populations for local areas which can be used by all the states. No other state agency has yet undertaken the specific task of projecting sex and age populations for the individual cities and towns, although other Massachusetts population projections are currently being developed. Therefore, the Division of Health Statistics and Research within the Department of Public Health has undertaken the development of such projections, and the methodology utilized is described below.

No one projection method can accommodate all the factors involved in population dynamics, and the methods vary in the items used; not surprisingly, therefore, the resulting projections vary. In the end, acceptance of a set of projections depends upon the acceptance of a given method's assumptions and logic, and the reliability and validity of the basic data available. One technique for projecting future numbers is to use national rates of change for the various components being projected, while at the other extreme, case studies of all individual towns of interest and their unique demographic dynamics could be conducted. The first approach uses rates so far removed from the area that the town's individuality is masked, while the second demands virtually unlimited resources. To meet the requirements for credibility, the Department of Public Health developed a method which uses the U.S. Bureau of the Census counts of residents by sex and age in all Massachusetts cities, towns, and census tracts for 1970 and 1980. This satisfies the need for completeness and consistency over time as well as throughout the geographic areas.

Methodology

Projections for 1980 and 1985 were prepared by the Department of Public Health in 1978. It was known at that time that new data collected and reported by the U.S. Bureau of the Census in 1980 would be used both to modify the 1985 projections and to develop a set for 1990.

The current methodology is essentially the same as that which produced the 1980/1985 set of projections. The underlying assumption is that the most recently documented change in the sizes of each municipality's sex/age groups is the best guide available to the Department for anticipating future changes. The most recently documented numbers are those reported by the U.S. Bureau of the Census for 1970 and 1980. They have the required standardization of definitions, collection, and reporting for all 351 cities and towns at the

two times. Standard demographic methods, with adaptations and modifications described below, were applied to the Census Bureau's reported 1970 and 1980 counts of persons in sex/age groups in each Massachusetts city and town.

The elemental measure of change is the Census Survival Rate (CSR). A CSR for each five-year age group (0-4, 5-9,...,70-74, 75+) for each sex in each town provides a measure of the change in numbers over the ten-year period 1970 to 1980. Each CSR can be used to project what the numbers in the sex/age groups will be ten years in the future (1990) assuming that the 1970-1980 trend will be continued to 1990. (The square root of the ten-year rate is used to project the midpoint, i.e., 1985, values, since the population change is considered to be an exponential rather than a linear function.)

The comparison of 1970 and 1980 Census data reflects changes due to mortality, migration, and fertility, and the projections reflect the combined effects of these elements. In-and out-migration rates are known to vary among sex/age groups and by geographic locality too, but these projections are of such short range that the ten-year Census Survival Rates are believed to serve adequately. We therefore have not done an analysis and identification of specific net migration rates or sex/age-specific mortality rates. The need for migration and mortality rates is recognized for long-range demographic forecasts, but they are not necessary for the Department's current purposes.

As noted above, the Census Survival Rate is a measure of change. It is calculated by comparing the 1980 number of persons in a given sex/age category in a given town with the number reported in that town in 1970 for that sex but ten years younger. The question being asked, for example, is: "How did the number of women 25-29 years old in Arlington change over a ten-year period?" The number of Arlington women 35-39 years old in 1980 is the answer. The Census Survival Rate differs from the mortality rate or life-expectancy rate in that its unit of concern is the number of persons and not the persons themselves. That is, the question is not how many 25-29 year-old women in Arlington will die or will move or will still be in Arlington aged 35-39 in 1980; it is not a cohort being followed. The CSR is a ratio of two numbers, and it is used to indicate the change that occurred in the denominator over a period of time. It is used, for instance, to say that, since the number of Arlington women aged 25-29 in 1970 declined by 28% over a ten-year period, we will project the number of Arlington's 25-29 year-old women in 1980 to be 28% fewer in 1990. The women 35-39 years of age in 1990 will therefore be projected to be 72% of the number of 25-29 year-old women in 1980, reflecting the changes which occurred between 1970 and 1980. The sex/age groups thus calculated, plus the projected unborn (discussed below), are summed to give each town's total population.

In order to reduce the aberrations caused by small numbers and/or atypical distributions, the CSR's for each of the Commonwealth's twenty-six HSA Subareas were used to project the sizes of the towns within the respective Subareas. The rationale called for having a geographic unit

larger than the town to provide stability, but with a similar demographic experience during the previous decade. To enhance the homogeneity within the Subareas, municipalities markedly dissimilar by size or composition were excluded from their Subarea's total and were projected individually.

There are some segments of the population, however, which cannot be subjected to the same reasoning. One such group is college students and another is military personnel. Students and armed forces members are counted by the Census Bureau as residents of their respective local areas of habitat, but they are not a constituent part of the aging community -- seniors leave and freshmen arrive, and the number and average age of students in a college town are not likely to vary appreciably. The problem with military personnel, on the other hand, is not so much the constancy of mean age as it is the simple impossibility of forecasting their numbers; such forecasts would depend upon information typically unavailable to demographers.

There is no reliable and valid count of students living on campus in all of the Commonwealth's schools of higher education. An approximation of the student population was derived by determining the proportion of the total State population of each sex who were 15-24 years old in 1980; these were then taken as the standards of reference. The proportions of males and females 15-24 years old in each town were compared with the State standards. In approximately thirty towns there were notable discrepancies for one or both sexes' proportions of student-aged persons. In those cases, closer attention was given to determine whether the age group was 15-19 and/or 20-24, male and/or female. The numbers exceeding the State's "normal" proportions were subtracted and temporarily set aside; similar adjustments were made for the 1970 "student" population. Census Survival Rates were calculated for the "normal" population and the projections were made in the usual manner. It was then that the excess "students" were returned to their respective age groups; i.e., the excess number of 20-24 year olds were returned to the 20-24 year-old group in 1985, and that number was also added to the 20-24 year-olds projected for 1990. The assumption here is that the college enrollments are going to remain the same for the ten-year period between 1980-1990.

With respect to the military population, Fort Devens required particular consideration. The military reservation is situated in three census tracts, one in each of the three towns of Ayer, Harvard, and Shirley. In 1970 the military census tracts accounted for 21%, 80%, and 19%, respectively, of the population in these towns; in 1980 the numbers were smaller but still appreciable. Given both that such large proportions of these towns' populations therefore had an atypical sex/age distribution and, furthermore, that changes in the number of personnel at a military establishment are subject to other than the usual demographic influences, the military populations were excluded when projecting anticipated changes in these towns' populations. The sex/age frequencies in the three tracts were held aside and only the civilian census tracts were used in the projection of each town's respective civilian population. For some planning purposes, perhaps, the military should be included; in that event, it is suggested that

the 1980 counts for the relevant census tracts be added to the population counts.

In addition, the Strategic Air Command at Westover Air Force Base in Chicopee was disbanded around 1973; the base is located in one census tract. For the projection of Chicopee's population, that census tract's 1970 and 1980 populations were omitted from the calculations. Otherwise, the marked change in the number of young men would have given a distorted Census Survival Rate that would have projected an unwarranted loss of population for Chicopee. Logically, all military populations should be treated similarly, but this is not possible because not all are similarly identifiable. For examle, the Otis Air Force Base is located in the town of Bourne, but there are no census tracts in that area and attempts to obtain numbers and ages of persons stationed there in 1970 and 1980 were unsuccessful.

Finally, a somewhat similar situation occurred in some towns in which State mental hospitals are located. The program of deinstitutionalization during the 1970's reduced the patient population of several of the facilities. Where the census tracts were identifiable, their populations were excluded when the CSR's were calculated.

The unborn (as of 1980) 0-4 and 5-9 year-olds were projected for each town in the following way:

(1) The male and female births for each town during the 1975-1979 years were summed. The annual number of births was divided by the number of females 15-44 years of age in 1980 to give town sex-specific General Fertility Rates. These rates were assumed to hold during the 1980's, and they were used with the numbers of childbearing-aged women in 1985 and 1990 to project the annual number of births to be expected, thereby providing a projected number of 0-4 year old boys and girls in 1985 and 1990.

(2) The number of births during the period 1975-1979 was compared with the 1980 count of 0-4 year-olds for each sex in each town; this gave a factor similar to a five-year Census Survival Rate for the 0-4 year-old group. This factor was used to modify the number of projected births to give a more reasonable number of 0-4 year-olds. Without this factor, there would have been no indicator of the effect of their parents' migration.

(3) The five-year CSR (for each sex) of the 0-4 year-old group was derived by comparing the 5-9 year-olds projected for 1985 with the Census count of 0-4 year-olds in 1980. (The 5-9 year-olds in 1985 had been projected by using the square root of the 1970 - 1980 CSR for 0-4 year-olds.) When this was applied to the projected number of 0-4 year-olds in 1985, an approximation of the number of 5-9 year-olds in 1990 was obtained.

Adjustments

The use of the Census Survival Rates can produce projections which appear to be unlikely or unreasonable even though they are

mathematically correct. The result in question can be either the total population or one or more of the sex/age frequencies for a particular municipality. A method for projecting sex/age distributions in Massachusetts towns for 1985 and 1990 must therefore also incorporate a credible set of adjustments which are necessitated by unique circumstances.

The first set of projections for 1990 were made by using each town's CSR's and then aggregating the sex/age groups. A list of all the towns arranged by HSA's with their respective 1970 and 1980 Census counts and the 1990 projections was circulated to recognized agencies and individuals with knowledge of local conditions for their comments and suggestions regarding the projected 1990 totals. The agencies included the six Health Systems Agencies and the thirteen Regional Planning Agencies. Two town planners were also contacted. The responses were considered, and modifications were made in some of the 1990 total populations where adequate explanations and documentation of the alternative numbers were provided.

The projected numbers of elderly (65+ years) and old (75+ years) persons in 1985 were derived by an exception to the rule of using the square-root of a ten-year Census Survival Rate to obtain a five-year projection. Generally, the square-root of the ten-year CSR gives a value closely approximating one-half of the ten-year change in the number of persons in a given age-group. The numbers of elderly in 1985 and 1990 are not a single age-group, however, but an accumulation of two age groups (60-64 and 65+) in 1980 and three age-groups (55-59, 60-64, and 65+) in 1980, respectively. Moreover, with increasing age, the rate of survivorship decreases more rapidly and the distributions in the older age groups are somewhat skewed. As a result, the use of the square-root of a ten-year CSR is inappropriate for this segment of the population.

Accumulating the three age-groups' counts as they were projected by the ten-year CSR's produced a total elderly population in the State for 1990 that was closely compatible with the trend in Massachusetts since the turn of the century. Consequently, after consultation with a demographer from the Harvard Center for Population Studies, the projected number of each town's elderly and old persons for 1985 was calculated as the number counted in the 1980 Census plus one-half the difference between it and the value projected for 1990. In short, the 1985 number is the mid-point between the 1980 and 1990 values.
